

# Evaluation Interfaces for AI Research Tools

## Abstract

Tool-using AI systems need evaluation interfaces that expose the run, not only the final answer. This manuscript describes a comparison interface for research tasks, with scenario inputs, tool traces, touched files, diffs, failure labels, and review records.

## Methodology

Each scenario defines the task, allowed tools, expected evidence, and review criteria. Runs are stored as structured traces with normalized summaries for comparison. The interface separates task outcome, process evidence, and failure classification so reviewers can inspect the run without replaying every step.

## Results

The proposed interface turns agent evaluation into a reviewable research object. It supports comparison across models and prompts while preserving the evidence needed to explain a pass, failure, or partial recovery.
